

# LITHIUM IN A METAL- POOR EXTERNAL GALAXY: $\omega$ CENTAURI

P. Bonifacio, L. Monaco, L. Sbordone,  
S. Villanova, E. Pancino

- This investigation is led by L. Monaco (Univ. Concepción, Chile)
- Based on data acquired with FLAMES @ VLT programme 079.D-0021(A)

# $\omega$ CENTAURI

- One of the brightest objects of the southern sky ( $V=5.33$ ) initially misclassified as star (hence the name, but also CD -46 8646, CPD -46 6348, HD 116790)
- Then classified as Globular Cluster (NGC 5139)
- It is currently accepted to be a satellite galaxy, the mass was probably larger in the past.

ESO / MPI 2.2m + WFI

# WHY IS $\omega$ CEN A GALAXY ?

- Its mass:  $3 \times 10^6 M_{\odot}$  is larger than any other GC
- Its orbit: large negative  $L_z$  (retrograde motion), but low total energy
- flattened shape, sizeable rotation
- highly complex stellar populations, different metallicities & ages

HST CMD of  
 $\omega$ Cen  
(Villanova et  
al. 2007)  
Combined  
with  
spectroscopic  
metallicities  
this allows  
relative ages  
accurate to  
0.2-1 Gyr

A Hess diagram clearly shows the highly complex population mix

The age span is greater than 5 Gyr

The metallicity distribution of the SGB from FLAMES blue spectra (Villanova et al. 2007)

(Piotto et al. 2005)

Surprise ! the blue Main Sequence is more metal-rich (by a factor of 2) than the red Main Sequence. This can be explained IF the bMS is HIGHLY He-rich

# WHAT CAN LI TELL US ?

- This is the first opportunity to probe Li in an external galaxy. Can falsify the “early destruction” mechanism of Piau et al. (2006, i.e. 50% of the mass of the Galactic Halo processes by Pop III stars to reconcile Spite Plateau with WMAP)
- The stars in  $\omega$  Cen span an age range of 5 Gyr, much larger than available in the Galactic Halo.
- If there are stars with  $Y=0.40$  in  $\omega$  Cen, then they should also be Li-free. We expect a large fraction of stars with no Li.

# FLAMES @ VLT

- 3 nights in April 2007, observer L. Monaco
- setting HR15n ( $H\alpha$  + Li)
- 30% of the time lost due to weather
- 9×2h observations for about 100 targets

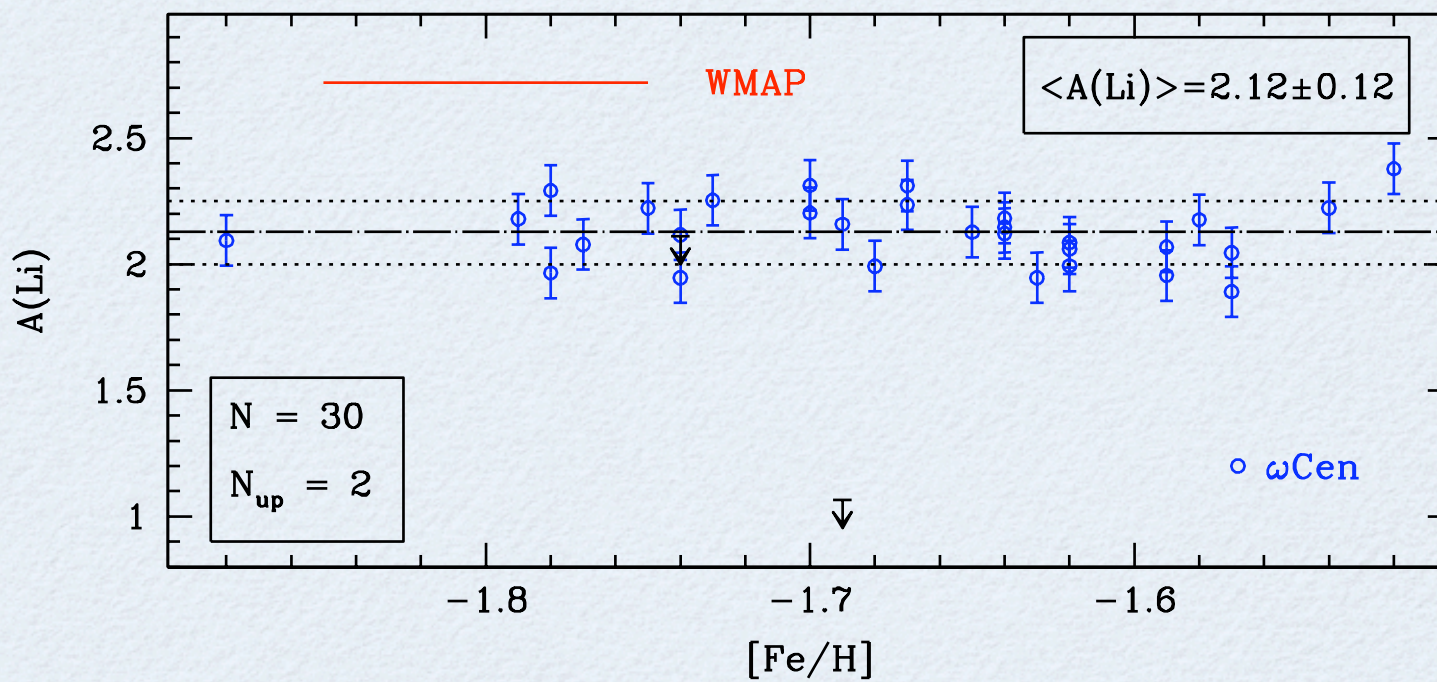

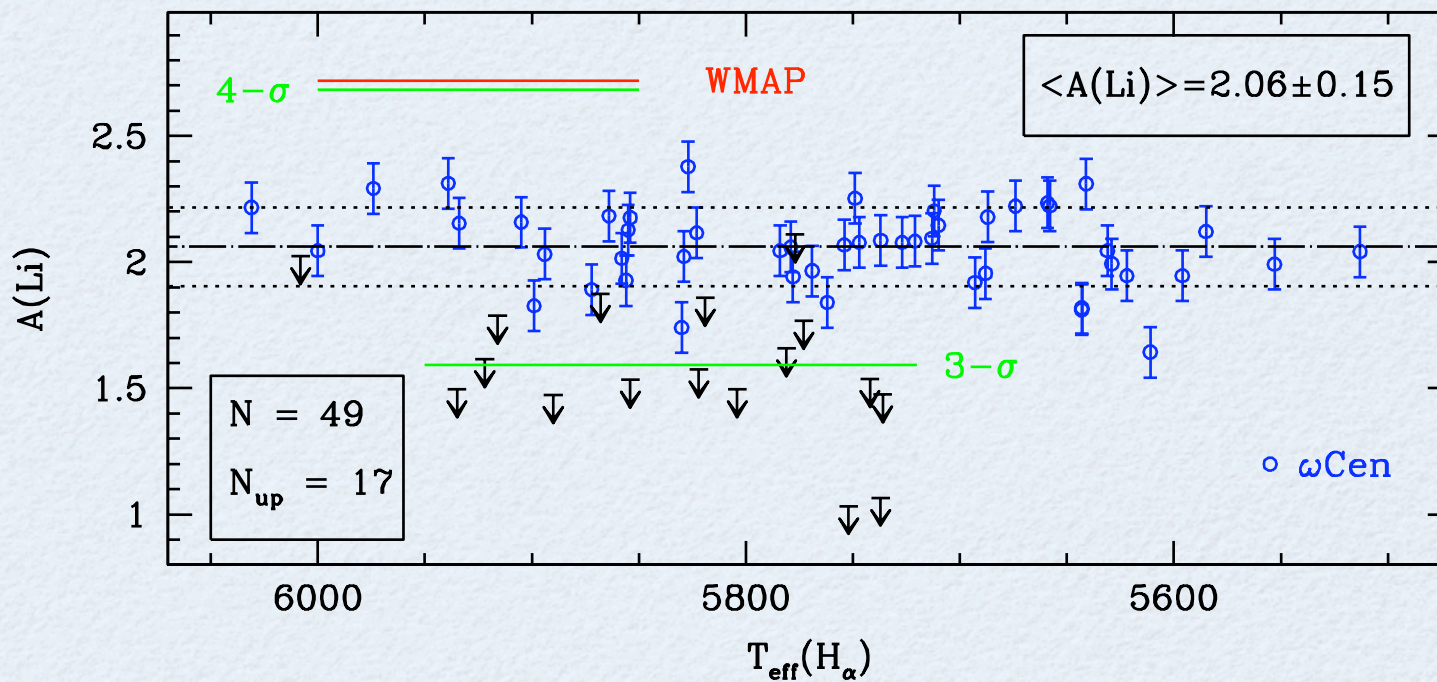

Teff from H $\alpha$  wings, Barklem et al. broadening, 1D ATLAS model atmospheres

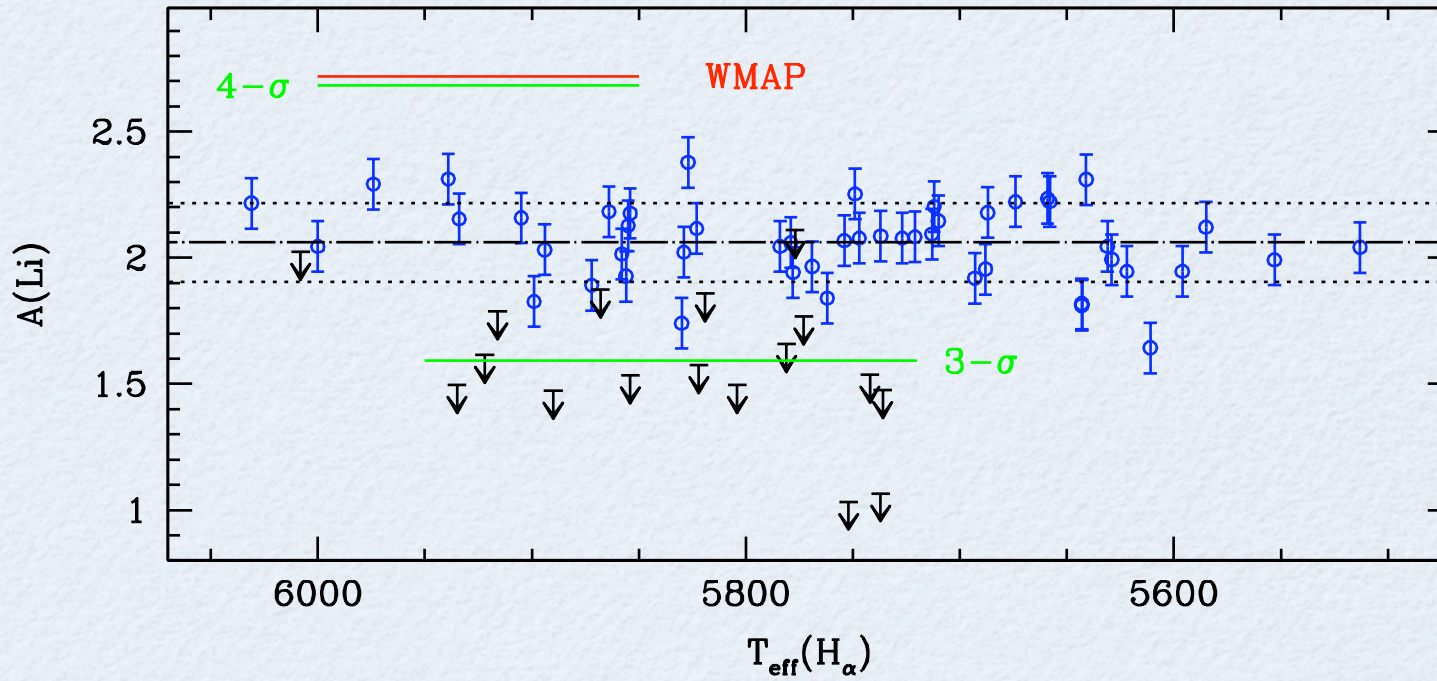

EW of Li from synthetic profile fitting, abundance from  
COG, (ATLAS model + SYNTHÉ)

# Così fan tutte ?

# Merci

(please do not shoot on the speaker)
